EX. 3:- IMPLEMENTATION OF BINARY SEARCH ALGORITHM

LO Mapped:- LO1, LO2

Binary Search is defined as a searching algorithm used in a sorted array by repeatedly dividing the search interval in half. The idea of binary search is to use the information that the array is sorted and reduce the time complexity to $O(\log N)$.

Conditions for when to apply Binary Search in a Data

Structure:

To apply Binary Search algorithm:

- The data structure must be sorted.
- Access to any element of the data structure takes constant time.

Binary Search Algorithm:

In this algorithm,

- Divide the search space into two halves by finding the middle index “mid”.
- Compare the middle element of the search space with the key.
- If the key is found at middle element, the process is terminated.
- If the key is not found at middle element, choose which half will be used as the next search space.
- If the key is smaller than the middle element, then the left side is used for next search.
- If the key is larger than the middle element, then the right side is used for next search.
- This process is continued until the key is found or the total search space is exhausted.

Consider an array `arr[] = {2, 5, 8, 12, 16, 23, 38, 56, 72, 91}`, and the **target = 23**.

First Step: Calculate the *mid* and compare the *mid* element with the key. If the key is less than *mid* element, move to left and if it is greater than the *mid* then move search space to the right.

- Key (i.e., 23) is greater than current *mid* element (i.e., 16). The search space moves to the right.

Binary Search Algorithm : Compare key with 16

- Key is less than the current *mid* 56. The search space moves to the left.

Binary Search Algorithm : Compare key with 56

Second Step: If the key matches the value of the *mid* element, the element is found and stop search.

Binary Search Algorithm : Key matches with mid

CODE:

```

//Binary Search
#include<stdio.h>

int binarySearch(int arr[], int l, int r, int x)
{
    if(r >= l)
    {
        int mid = l + (r - l) / 2;

        if (arr[mid] == x)
            return mid;

        if(arr[mid] > x)
            return binarySearch(arr, l, mid - 1, x);

        return binarySearch(arr, mid + 1, r, x);
    }
    return -1;
}

int main()
{
    int x;
    int arr[] = {2, 3, 17, 21, 42, 69, 71, 90, 97};
    int n = sizeof(arr) / sizeof(arr[0]);
    printf("Enter the element you want to find: ");
    scanf("%d",&x);
    int result = binarySearch(arr, 0, n - 1, x);
    (result == -1) ? printf("Element is not present in the array") : printf("The element is present at index
%d", result);
    return 0;
}

```

OUTPUT:

```
32     int x;  
33     int arr[] = {2, 3, 17, 21, 42, 69, 71, 90, 97};  
34     int n = sizeof(arr) / sizeof(arr[0]);  
35     printf("Enter the element you want to find: ");  
36     scanf("%d",&x);  
37     int result = binarySearch(arr, 0, n - 1, x);  
38     (result == -1) ? printf("Element is not present in array") : printf("Element is present at index %d", result);  
39     return 0;  
40 }  
41
```

Enter the element you want to find: 42
The element is present at index 4

...Program finished with exit code 0
Press ENTER to exit console.

CONCLUSION:

We can conclude that we have successfully implemented Binary Search algorithm.
